## Abstract

About 40% of asthmatics experience remission of asthma symptoms. A better understanding of biological pathways leading to asthma remission may provide insight into new therapeutic targets for asthma. As an important mechanism of gene regulation, investigation of DNA methylation provides a promising approach. Our objective was to identify differences in epigenome wide DNA methylation levels in bronchial biopsies between subjects with asthma remission and subjects with persistent asthma or healthy controls.

We analysed differential DNA methylation in bronchial biopsies from 26 subjects with persistent asthma, 39 remission subjects and 70 healthy controls, using the limma package.

The *comb-p* tool was used to identify differentially methylated regions. DNA methylation of CpG-sites was associated to expression of nearby genes from the same biopsies to understand function.

Four CpG-sites and 42 regions were differentially methylated between persistent asthma and remission. DNA methylation at two sites was correlated *in cis* with gene expression at *ACKR2* and *DGKQ*, respectively. Between remission subjects and healthy controls 1163 CpG-sites and 328 regions were differentially methylated. DNA methylation was associated with expression of a set of genes expressed in ciliated epithelium.

CpGs differentially methylated between remission and persistent asthma identify genetic loci associated with resolution of inflammation and airway responsiveness. Despite the absence of symptoms, remission subjects have a DNA methylation profile that is distinct from that of healthy controls, partly due to changes in cellular composition, with a higher gene expression signal related to ciliated epithelium in remission versus healthy controls.

## Background

Asthma is a chronic inflammatory disease of the airways, characterized by variable airflow obstruction associated with symptoms of wheezing, shortness of breath, chest tightness and coughing. Chronic inflammation in asthma is associated with remodeling of the airways, e.g. increased basal membrane thickness, airway epithelial shedding, increase of goblet cells, increased mucus production and increase of smooth muscle mass [1]. Interestingly, in some asthma patients, symptoms disappear over time, and the need for pulmonary medication ceases. The prevalence of asthma is highest between 10 and 25 years and gradually decreases at higher age, the latter indicating that asthma remission rates have become higher than incidence rates [2]. In adulthood, the average remission rate of asthma is approximately 2% per year, with a higher chance to go into remission with an earlier onset of asthma, less severe airway obstruction, and cessation of smoking [3, 4]. A subset of patients with asthma in remission still have airway obstruction and/or show airway hyperresponsiveness (AHR) in provocation tests [5]. Vonk *et al.* [6] therefore introduced the terms ‘clinical remission’ and ‘complete remission’. Clinical remission is defined as the absence of asthma symptoms and no use of asthma medication. Complete remission of asthma is defined as the absence of asthma symptoms, no use of asthma medication, normal lung function and no AHR.

We still have minimal understanding of the cellular and molecular mechanisms that determine whether or not asthma persists or undergoes apparent spontaneous resolution. As for asthma development, genetic and environmental factors are likely to be involved in asthma remission as well [7]. The effect of both genetic and environmental variation on health outcome is often mediated by differences in gene transcription [8]. The methylation of cytosine at CpG-sites is an important epigenetic modification that regulates transcription by affecting several

mechanisms [9]. Variation in DNA methylation at CpG-sites has been associated with asthma and other atopic diseases [10–15]. This warrants further investigation of this type of epigenetic variation.

In order to identify molecular mechanisms related to asthma remission in the airways, we investigated whether variation in DNA methylation in bronchial biopsies is associated with remission of asthma. Our main aim was to detect CpG-sites that are differentially methylated between well characterized subjects in complete and clinical remission and subjects with persistent asthma or healthy controls. In addition, we investigated how differentially methylated CpG-sites associate with the expression levels of nearby genes in these bronchial biopsies, and related these to candidate molecular and cellular pathways. This furthers our ultimate aim to identify cellular mechanisms related to asthma remission in the airways.

## **Methods**

### Subjects

From previous studies [16, 17] biopsies were available from clinically well characterized subjects with clinical remission (ClinR,  $n = 33$ ), complete remission (ComR,  $n = 15$ ), persistent asthma (PersA,  $n = 90$ ). Biopsies from healthy controls (H,  $n = 94$ ) were available from another study. The study design and methods have been published previously [16, 17]. The subjects with ClinR and ComR had a documented diagnosis of asthma, confirmed by AHR testing [6, 17]. Asthma was defined as documented reversibility and/or AHR to histamine ( $PC_{20} \leq 32$  mg/mL). Subjects were considered to be ClinR if they had not had an asthma attack or wheeze in the last 3 years, and did not use asthma medication ( $\beta$ -agonists and ICS). Asthma patients were considered to be ComR if they, in addition to the previous criteria,

did not have AHR to both histamine and AMP ( $> 32$  mg/mL in 30 s tidal breathing and  $> 320$  mg/mL in 2 min tidal breathing respectively) and had no signs of airflow obstruction ( $FEV_1$  %predicted  $> 80\%$  pre bronchodilator or  $>90\%$  post bronchodilator). The subjects with PersA were divided on the basis of use of inhaled corticosteroids (ICS), since corticosteroids are known to affect gene expression and may act as a confounder on DNA methylation as well [18]. The non-asthmatic healthy controls were recruited from the NORM study (clinical trials number NCT00848406) and were all current smokers and never smokers older than 18 years. Subjects were considered healthy if they had no respiratory symptoms, no history of respiratory disease and normal pulmonary function defined as a post bronchodilator  $FEV_1/FVC$  higher than the lower limit of normal, absence of AHR to methacholine ( $PC_{20} > 16$  mg/mL) and absence of  $FEV_1$  reversibility (increase  $FEV_1$  after 400  $\mu$ g salbutamol  $< 10\%$  of the predicted  $FEV_1$  value). Healthy subjects were excluded if they had used inhaled or oral corticosteroids within the last 5 years, or during a total of 5 years of their lives. Biopsies from healthy subjects were collected between 2009-2012 and biopsies from all other subjects between 2005-2007. All subjects were included in the same center (UMCG) and bronchoscopies and processing of samples were performed by the same team. For RNA and DNA extraction and further processing, an even distribution of case-control status, age, gender and smoking status among batches was carefully controlled during all steps in the experimental design. Details on the DNA/RNA extraction, sample preparation and QC are provided in the supplementary methods. The study protocol was approved by the local medical ethics committee. All subjects gave their written informed consent.

### DNA methylation

DNA methylation levels were measured in bronchial biopsies using the Infinium HumanMethylation450 BeadChip array (450k array) (Illumina, San Diego, CA). Raw intensity data were processed using the minfi package [19]. Samples and probes failing QC were removed and raw beta values normalised using the dasen method as implemented in the watermelon package [20]. DNA methylation levels at each CpG-site were expressed as beta-values, ranging from zero (no methylation) to one (complete methylation). A detailed description can be found in the supplementary methods. An overview of the sample dropout during QC is shown in Supplementary Figure 1a.

### RNA sequencing

RNA samples from airway wall biopsies were processed using the TruSeq Stranded Total RNA Sample Preparation Kit (Illumina, San Diego, CA). The cDNA fragment libraries were loaded onto an Illumina HiSeq2500 sequencer for paired-end sequencing ( $2 \times 100$  bp). Trimmed fastQ files were aligned to build b37 of the human reference genome using HISAT (version 0.1.5) and gene level quantification was performed by HTSeq (version 0.6.1p1) using Ensembl version 75 as gene annotation database [21]. A detailed description can be found in the supplementary methods. An overview of the sample dropout during QC is shown in Supplementary Figure 1b.

### Differential methylation analysis

Differential methylation between subject groups was assessed for each probe using robust linear modelling in the limma package [22, 23]. To remove heteroscedasticity, beta-values were logit-transformed to M-values [24]. M-values were used as the dependent variable in all

analyses. Age, gender and current smoking status were corrected for. In addition, the principal components explaining 95% of the variation in the control probes were used as covariates to correct for technical variation [25]. We also analysed a model that included ex-smoker status in addition to current smoking, and found consistent results with the majority of DMRs remaining above the significance threshold. In remission vs asthma, of the 46 CpGs plus DMRs, 42 (91%) remained significant. In remission vs. healthy from the 1491 CpGs plus DMRs, 1223 remained significant (82%), but as this did not appreciably affect the results, these data will not be presented. We analyzed five subject categories; persistent asthma using ICS (PersA\_ICS), persistent asthma not using ICS (PersA\_no\_ICS), ClinR, ComR and H. We pooled ClinR and ComR to increase sample size. We specified two contrasts: [ComR + ClinR] vs. PersA\_no\_ICS and [ComR + ClinR] vs. H. We refer to those contrasts as “remission vs. asthma” and “remission vs. healthy” respectively. To avoid the confounding of ICS use, we focused on the group of asthmatics without ICS. We applied correction for multiple testing by controlling the false discovery rate at 5% using the Benjamini-Hochberg method [26]. The most significant hits of individual CpG-sites were annotated to the nearest gene using information from the IlluminaHumanMethylation450kanno.ilmn12.hg19 annotation package, or when no annotation was provided we searched the UCSC genome browser [27, 28].

### Differentially Methylated Regions (DMRs)

Regions of correlated CpG-sites with differential methylation were identified using the comb-p v0.48 command line tool and python library [29]. We used the pipeline with seed setting  $P = 0.05$  and distance 750 bp. The region filter settings were  $n = 2$  and a Sidak-corrected  $P = 0.05$ .

### Association between DNA methylation and gene expression (eQTM mapping)

We used the MatrixEQTL package to determine whether DNA methylation levels at CpG-sites were associated with gene expression levels of nearby genes within 1 Mb of the CpG-site [30]. Raw read counts from RNA sequencing were normalized for library size using the weighted trimmed mean of M-values (TMM) method as implemented in the edgeR package [31]. The normalised counts were transformed to  $\log_2(\text{Counts Per Million})$ . We used methylation M-values as the explanatory variable and age, gender and current smoking status were set as covariables.

### Cell type composition

Surrogate variable analysis (sva) provides estimates of latent variables, which is recommended as substitute for cell type deconvolution [32]. A detailed description can be found in the supplementary methods. We performed this analysis for all FDR-significant differentially methylated CpGs from remission *vs.* asthma and the ten most differentially methylated CpGs from remission *vs.* healthy.

We also took a targeted approach to the analysis of cell type composition, by extending the method proposed by Xu *et al.* [13]. For the same set of CpG-sites as used in the surrogate variable analysis, we performed genome wide mapping of DNA methylation to gene expression. For each CpG-site, the resulting set of test statistics was used as input for mean-rank gene set enrichment analysis as implemented in limma [33]. We tested enrichment of 20 gene sets expressed by the cell type clusters taken from single cell sequencing results of airway wall biopsies as reported in Vieira Braga *et al.* [34].

## Results

### Patient characteristics

We obtained DNA methylation data for 179 samples, after excluding 53 samples that were lost during processing or excluded during the QC procedure (Supplementary Figure 1). Of the included samples, 12 subjects had ComR, 27 subjects ClinR, 70 subjects PersA and 70 subjects were H. Of the PersA subjects, 26 were not using ICS. The patient characteristics of the 5 subject groups are presented in Table 1.

### Differential methylation in remission vs. persistent asthma

Methylation levels at four individual CpG-sites and 42 regions were significantly different in remission vs. asthma (Table 2A, 3A). The most significant site was cg08364654, which showed 6% lower methylation in remission subjects than in asthmatics (Figure 1A). This CpG is also part of the most significant DMR on chromosome 3 (Table 3A). All CpGs in the DMR are located in the *KRBOX1* gene, but we did not find these CpGs to be associated with *KRBOX1* expression. Instead, a higher methylation was associated (most significantly at cg22714811 at  $P = 7.9 \cdot 10^{-4}$ ) with increased expression of the atypical chemokine receptor 2 (*ACKR2*) gene (Figure 2A; Figure 3). The second CpG-site (cg23805470) also had 2% lower methylation in subjects in remission compared to persistent asthmatics. Methylation of cg23805470 was not significantly associated with expression of the gene it resides in (*tenascin XB*, *TNXB*) or any other nearby gene. The third site cg13525448 lies in an exon of *ladybird homeobox 1* (*LBX1*), but was not associated with gene expression in *cis*. It had 2% higher methylation in remission than in persistent asthma (Figure 1C). The fourth CpG-site (cg00741675) had 11% lower methylation in remission and is located in the 5'UTR of the diacylglycerol kinase, theta 110kDa (*DGKQ*) gene. It did not associate with gene expression

at the  $P = 0.001$  cut-off, but is positively associated with gene expression of *DGKQ* at  $P < 0.004$  (Figure 2B). The second significant DMR is located at chromosome 19 and associated with expression of *RPL13A*. The encoded product is a component of the IFN-gamma-activated inhibitor of translation (GAIT) complex, which plays a role in the repression of inflammatory genes and contributes to the resolution of chronic inflammation [35]. Among the four significant individual CpG-sites from the contrast remission *versus* asthma (Table 2A), all remained significantly differentially methylated (at  $P < 0.001$ ) after correction for the first five surrogate variables, indicating that the differences in methylation were not driven by cell type composition (Table 2A, Supplementary Figure 2A). Significance of cg00741675 dropped sharply, but for all four CpGs log fold changes remained similar after adjustment.

#### Differential methylation in remission vs. healthy

We found 1163 individual CpG-sites and 328 regions to be differentially methylated between remission subjects and healthy controls, with one-third of the individual sites and 20% of the DMRs being higher methylated in remission (Table 2B and 3B show the top10, complete list in Supplementary Table 1B and 2B). Of the 1163 significant CpG-sites, 167 were located in a DMR. Correction for surrogate variables resulted in similar log fold changes but did appreciably affect the significance of the ten most significant CpG-sites, suggesting an impact of cell type composition in the contrast remission versus healthy (Supplementary Figure 2). To further investigate effects of cell type composition we identified cell type specific gene expression profiles by associating methylation levels of the ten most significant CpG-sites to genome-wide gene expression levels. Then we compared associated genes to gene sets characteristic for 20 major clusters of cells found in bronchial biopsies based on single cell sequencing data [34]. All ten tested CpG-sites from the contrast remission *vs.* healthy showed

strong enrichment for association with genes belonging to multiple sets of cell types (Supplementary Table 3). Highest enriched groups throughout were ciliated epithelial cells and basal cells. Several CpGs were most significantly enriched for other groups though: smooth muscle cells (cg06947286 and cg10986462), fibroblasts (cg23916878), neutrophils (cg18763536) and T-cells (cg08307963) (Figure 4a). Nine out of ten tested CpG-sites from the contrast remission *vs.* healthy showed strong enrichment ( $P \ll 0.001$ ) for highly ranking genes from ciliated epithelium (Figure 4). We tested whether the enrichment was due to the underlying correlation structure of our data set, but this did not fully account for our findings. For comparison, only 49% of a randomly selected sample of CpG-sites has enrichment for this gene set at this significance level. In addition, five of ten tested CpG-sites belong to the top 1% enrichment as judged by comparison to  $P$ -values in the randomly selected sample. Figure 4B shows the ranking of correlated genes of a representative CpG-site from this set (cg07224931). Nearly all genes in the set related to ciliated epithelium have higher gene expression in remission versus healthy controls (99 %).

## Discussion

We found four individual CpG-sites and 42 regions to be differentially methylated between subjects in remission and persistent asthmatics. Of the individual CpGs two associated with gene expression of *ACKR2* and *DGKQ*, respectively. These four CpGs were not strongly related to cell type composition of the airway wall biopsy. There were 1163 CpG-sites and 328 regions differentially methylated between remission subjects and healthy controls. Many of the highly significant CpG-sites that distinguish remission subjects from healthy controls were associated with increases in the expression of genes associated with ciliated epithelial cells, consistent with cell type composition differences in remission *versus* healthy. We found

differences in absolute methylation between groups between 2% and 11%. It should be noted that even modest differences can be relevant when they reflect changes within a specific cell type.

The most significant CpG site, as well as DMR, with lower methylation in the contrast remission vs. asthma was associated with lower expression of *ACKR2* in subjects with remission. This gene contributes to resolution of inflammation by post-inflammatory clearance of chemokines in a mouse model [36]. Allergen-challenged mice that are deficient for *ACKR2* have more infiltrating cells in the airways, primarily dendritic cells and eosinophils. Interestingly, these *ACKR2*-deficient mice have less airway reactivity to methacholine [37]. We suggest that lower expression of *ACKR2* may play a role in the remission of asthma, by reducing AHR. Of interest, the lower methylation and *ACKR2* gene expression was paralleled by decreased airway reactivity in the *ACKR2* deficient mice, but not by reduced inflammation as would be expected. The CpG-site in *TNXB* could not be related to expression of this gene, but tenascin genes are known to be important in airway remodeling [1]. Multiple CpG-sites in *TNXB* were less methylated in primary airway epithelium cells (AEC) after exposure to IL13, a type 2 cytokine and key mediator of airway inflammation and remodeling in asthma [15]. *TNXB* resides in the HLA class II region, which is important for immune function [38], but we were unable to link differential methylation at cg23805470 to expression of HLA genes. CpG-site cg00741675 in *DGKQ* has lower methylation in remission subjects when compared to persistent asthmatics. *DGKQ* encodes a member of the family of diacylglycerol kinases (DGKs) that attenuate levels of the second messenger diacylglycerol in cells by converting it to phosphatidic acid [39]. The precise mechanism by which it may be involved in the remission of asthma is not clear, but members of the DGK

family are expressed in immune cells, and thus may be required for proper cellular signaling in inflammatory processes [40].

Subjects in remission have a methylation profile that is distinct from that of persistent asthmatics, which may reflect differential regulation of immune functions. However, their methylation profile does not resemble the healthy situation either. Individuals with complete asthma remission retain characteristics that differ from healthy subjects without a history of asthma, for example, persistent airway remodeling as shown by increased basal membrane thickness [17]. Analogous to this situation, we find methylation differences between remission and healthy that do not occur between remission and asthma. We found 21 out of 42 DMRs and 3 out of 4 differentially methylated CpGs in remission vs. asthma to overlap DMRs found in asthma vs. healthy. For remission vs. healthy this concerned 126 out of 327 DMRs and 310 out of 1163 differentially methylated CpGs. This clearly shows that differential methylation in both the remission vs. asthma and the remission vs. healthy contrasts capture aspects of methylation differences between persistent asthmatics and healthy subjects, consistent with the intermediate position of remission subjects. A possible explanation is that subjects in asthma remission still display an epigenetic fingerprint of asthma. A similar lingering difference in methylation profiles was reported for ex-smokers [41]. Alternatively this may reflect an inherent predisposition to developing asthma, which puts remission subjects at an increased risk for relapse.

A strength of our design is the use of bronchial biopsies, which enabled us to study epigenetic profiles in the relevant tissue. Also, we included healthy subjects and well characterized subjects in clinical and complete remission. All remission subjects had previous objective

confirmation of their asthma diagnosis with detailed follow up. Finally, we added functional information to differentially methylated CpG-sites by their association with the expression levels of nearby genes, using the same biopsy as used for determination of methylation levels. One limitation is the absence of an independent replication cohort in which bronchial biopsies are available for remission subjects and healthy controls. To the best of our knowledge, no comparable replication cohort with a similar design is available. Another issue is that differential methylation among subject groups was partly driven by differences in cell type composition, which hampers identification of specific asthma or remission related CpG-sites. By annotating the associated CpGs with gene expression, we show that subjects in remission differ from healthy controls in methylation levels at CpG-sites associated with multiple cell types, and that there is strong enrichment of CpGs in genes associated with ciliated epithelium. A possible interpretation is that changes in the cell type composition, in particular the proportion of ciliated epithelium in remission subjects explains part of the differential methylation between remission subjects and healthy controls. This is supported by the inflation of the *P*-values in this particular contrast. The prominent signal from epithelium may reflect the abundance of this cell type in biopsies, and the importance of other cell types in asthma and remission should not be neglected, but it emphasises that the airways of subjects in remission still have not come to resemble the healthy profile.

### Acknowledgements

We wish to thank Pieter van der Vlies, Bahram Sanjabi, Desiree Brandenburg-Weening and Harold de Bruin for their valuable work in the DNA extraction, sample preparation and hybridization.

### Author's contributions

CJV performed differential methylation analysis and drafted and finalized the manuscript, C-JX and JMV were involved in data management, data analysis and editing the manuscript, NHTtH, WT, IHH, MCN, AJvO, KA and GHK provided guidance and technical knowledge and edited the manuscript, JB performed eQTM analysis, MW contributed expression and methylation data, MvdB, NHTtH, WT and JMV were involved in the design of the study and MvdB drafted parts of the manuscript. All authors approved the final manuscript.

### Competing interests

KA and AJvO are employees of GlaxoSmithKline.

### Funding statement

Data were generated as part of a Scientific Research Collaboration funded by GSK.

## Figure Legends

**Figure 1:** Violin plots of highly differentially methylated CpG-sites in the “asthma *vs.* remission” contrast. (A) cg08364654 in the *KRBOX1* gene (B) cg23805470 in the *TNXB* gene (C) cg13525448 and (D) cg00741675 in the *DGKQ* gene. Subject groups: PersA\_ICS Persistent asthma with ICS use PersA\_no\_ICS Persistent asthma without ICS use, ClinR Clinical Remission, ComR Complete Remission, H Healthy Controls.

**Figure 2:** Correlation of DNA methylation at differentially methylated CpG-sites with gene expression of nearby genes. The groups used in the contrasts (either “remission *vs.* asthma” or “remission *vs.* healthy” ) are marked with non-gray colors; remission in yellow, asthma in red, healthy in blue. Subject groups (PersA\_ICS Persistent asthma with ICS use PersA\_no\_ICS Persistent asthma without ICS use, ClinR Clinical Remission, ComR Complete Remission, H Healthy Controls) are indicated with different symbols.

**Figure 3:** CoMET plot of the genomic region of cg08364654. The top plot shows the strength of correlation with expression of the *ACKR2* gene for all the CpG-sites in the interval. The plot below shows the strength of association in the remission *versus* asthma contrast. Red symbols indicates positive and blue symbols negative associations. The default coMET annotation tracks were plotted: ENSEMBL genes, CpG islands, chromatin-state (Broad institute), DNase sensitive regions and SNPs. See coMET documentation for detailed description. The bottom plot shows a correlation matrix of DNA methylation among all plotted CpG-sites.

**Figure 4:** Effect of cell type composition on average methylation levels. Effect of cell type composition was gauged by genome wide correlations with gene expression. A) Heatmap and hierarchical clustering of  $-\log_{10}(P\text{-values})$  of mean-rank gene set tests on the test statistics of DNA methylation - gene expression correlations. The CpG-sites are the four most significant sites from the contrast remission *versus* asthma (R *vs* A) and the ten most significant hits from the contrast remission *versus* healthy (R *vs* H). The gene sets distinguish the four main clusters of epithelial cell types in single cell sequencing. See the MS for details. B) Ranks of test statistic for a selected CpG-site (cg07224931) demonstrates the enrichment of highly ranking genes of the ciliated epithelium.

## Tables

**Table 1: Patient characteristics.**

Characteristic	PersA_ICS	PersA_no_ICS	ClinR	ComR	H	H <sub>0</sub> : No differences between groups. test-statistic; df; <i>P</i> -value

PersA persistent asthma, ClinR clinical remission, ComR complete remission, H healthy. Frequency data were analysed with chi-squared tests of independence. Differences in continuous variables were tested with oneway ANOVA. Variables were transformed, if necessary, to satisfy the assumption of normality. For FEV1 and FEV1/FVC ANOVA was performed on z-values (GLI2012\_DataConversion software). When PC<sub>20</sub>AMP was not reached at the highest dose, values were obtained by extrapolating from an exponential decay dose response curve. No appropriate transformation for PC<sub>20</sub>AMP was found, and these data were analysed by oneway ANOVA based on a permuted distribution of F with 1000 permutations [42]

Toptables of the contrasts (A) “remission versus asthma” and (B) “remission versus healthy”. The tables show the Probe ID, with its genomic position (hg19), the name of any nearby genes and its position relative to that gene, proximate genes with associated expression, the log2 fold change of the beta values, the moderated t-value and its associated probability of the null-hypothesis of no difference between the groups, as well as the adjusted P-value by Benjamini-Hochberg correction controlling the FDR at 5%. The rightmost column lists the P values of the analysis where surrogate variables were added as covariates (see text). Positive logFC indicate higher methylation in asthmatics than remission subjects in 2A and higher methylation in remission subjects than healthy controls in 2B.

Top tables of the contrasts (A) “remission *versus* asthma” and (B) “remission *versus* healthy”. The tables show the genomic position (hg19), the number of probes in the DMR, the one-step Sidak corrected *P*-value, the summed *t*-value, the name of any nearby genes and CpG positions relative to that gene, and proximate genes with associated expression. Positive *t*.sum values indicate higher methylation in asthmatics than remission subjects (Table 3A) and higher methylation in remission subjects than healthy controls (Table 3B).

## Supplementary Materials and Methods

### DNA / RNA extraction

Bronchial biopsies were taken from segmental divisions of the main bronchi and immediately frozen in Tissue-Tek (VWR, Radnor, PA) at -80°C. After thawing at room temperature, biopsies were cut from the blocks when they were semi-solid. Samples were lysed in 600 µl RLT-plus using a IKA Ultra Turrax T10 Homogenizer. Total genomic DNA was extracted using AllPrep DNA/RNA/miRNA Universal Kit, according to the manufacturer's instructions (Qiagen, Venlo, the Netherlands). DNA samples were dissolved in 30 µl elution buffer. Concentrations of DNA were measured in 1 µl of fluid using a Nanodrop-1000 and in 2 µl of fluid run on a Labchip GX (Perkin Elmer, Waltham, MA).

### DNA methylation: Sample preparation and Hybridization protocol

DNA samples were purified by a precipitation step, rinsed with ethanol (70%) and dissolved in elution buffer. Then, samples were treated with sodium bisulfite to convert unmethylated cytosine bases into uracil. This was followed by a PCR-free whole genome amplification, after which the treated DNA was hybridized to the Infinium HumanMethylation450 BeadChip array (450k array). After hybridization, allele-specific single-base extension incorporated a fluorescent label for detection of methylated and unmethylated sites. The conversion and hybridization protocol was performed according to the manufacturer's instructions (Illumina, San Diego, CA).

Every beadchip was run with a control sample of blood DNA from a single female, which was used to assess the efficiency of the normalization procedure by verifying that the among sample variance was minimized. We used a randomized block design, where samples were assigned to blocks based on subject group, smoking status and gender, and randomized within blocks.

### DNA methylation: Quality control, sample filtering, probe filtering and normalization

Raw intensity values were read from IDAT-files, and converted to beta values using the minfi-package [1]. We identified bad quality samples using the R-package MethylAid, based on five diagnostic filter variables with the following thresholds; MU = 10.5, OP = 11.75, BS = 12.5, HC = 13.25, and DP = 0.95 [2]. Genotypes from 65 SNP probes on the 450k array were compared to previously acquired genotypes from blood samples and discordant samples were discarded as swapped or contaminated samples and excluded from the analysis.

We excluded probes where >1% of samples had intensities indistinguishable from background levels at  $P = 0.05$ , probes which were crossreactive [following 3], probes which have SNPs with MAF > 10% at the interrogation or extension site, and type I probes which displayed high intensity

signals [following 4]. In addition, we excluded all sex linked probes. The probe filtering procedure resulted in the removal of 48,059 unreliable probes (10 %). After probe-and sample-filtering, raw beta-values were background-corrected and normalized using the dasen method from the watermelon-package [5].

#### DNA methylation: Correction for cell type composition

We investigated how corrections for cell type composition affected the results for a subset of differentially methylated CpG sites. We estimated surrogate variables from our DNA methylation levels as implemented in the sva package and added those to our basic model as covariates [6]. This is a reasonable alternative to deconvolution using reference cell type profiles [7]. We reran the linear modelling analysis and monitored how this impacted the significance of the differential methylation in the contrasts.

#### RNA sequencing: Sample preparation and sequencing

RNA samples were further processed using the TruSeq Stranded Total RNA Sample Preparation Kit (Illumina, San Diego, CA), using an automated procedure in a Caliper Sciclone NGS Workstation (PerkinElmer, Waltham, MA). In this procedure, all cytoplasmic and mitochondria rRNA was removed (RiboZero Gold kit). The obtained cDNA fragment libraries were loaded in pools of multiple samples into an Illumina HiSeq2500 sequencer using default parameters for paired-end sequencing ( $2 \times 100$  bp).

#### RNA sequencing: Gene expression quantification

The trimmed fastQ files were aligned to build b37 of the human reference genome using HISAT (version 0.1.5) allowing for 2 mismatches [8]. Before gene quantification SAMtools (version 1.2) was used to sort the aligned reads [9]. The gene level quantification was performed by HTSeq (version 0.6.1p1) using Ensembl version 75 as gene annotation database [10].

#### RNA sequencing: Quality Control

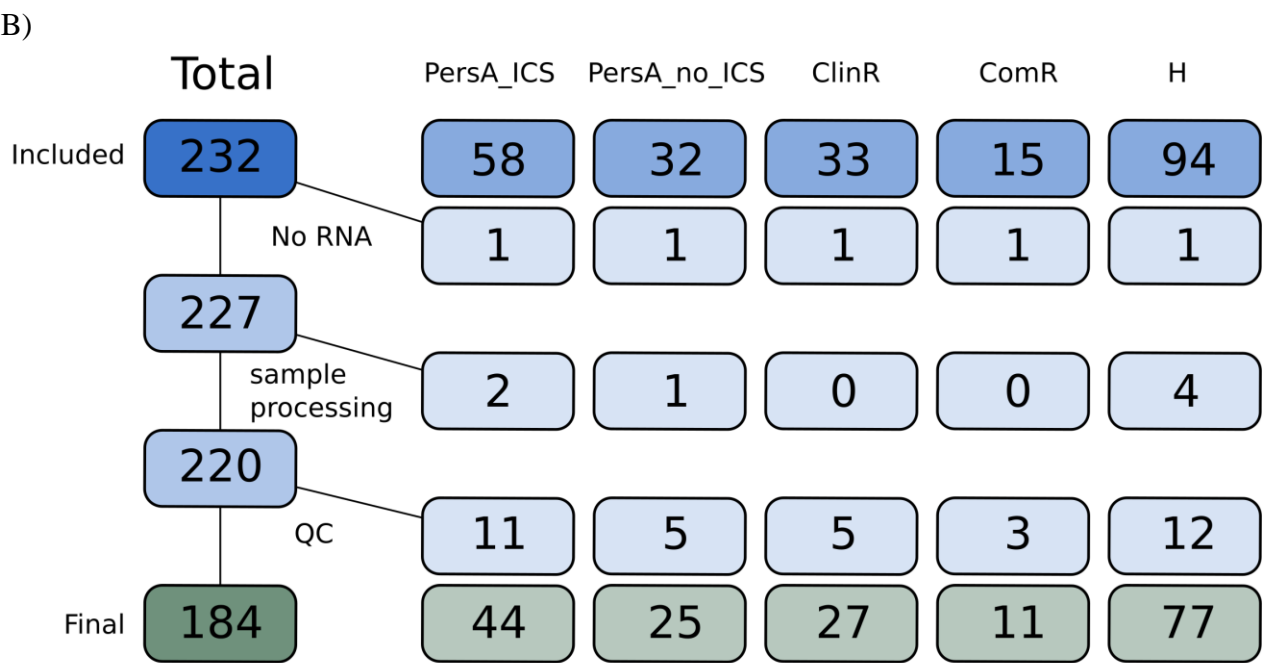

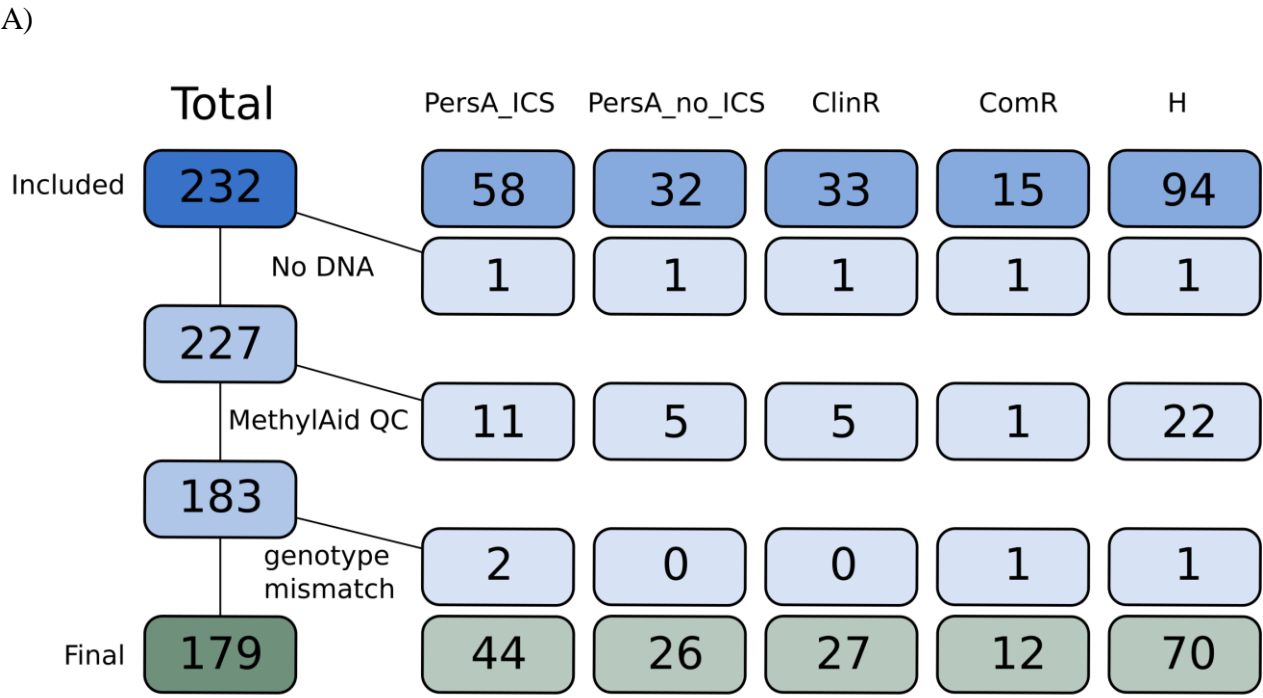

Quality control (QC) metrics were calculated for the raw sequencing data, using the FastQC tool (version 0.11.3) [11]. Alignments of 220 subjects were obtained. QC metrics were calculated for the aligned reads using Picard-tools (version 1.130) (URL <http://picard.sourceforge.net>) CollectRnaSeqMetrics, MarkDuplicates, CollectInsertSize-Metrics and SAMtools flagstat. We discarded 36 samples due to poor alignment metrics. In addition, we checked for concordance between sexlinked (XIST and Y-chromosomal genes) gene expression and reported sex. All samples were concordant. This resulted in high quality RNAseq data from 184 subjects.

# Supplementary Figures

**Figure 1:** Sample drop out during QC for A) DNA methylation array and B) RNAsequencing samples. The upper tier (dark blue) shows the total numbers of included subjects and the bottom tier (in green) shows the total numbers of samples analysed in this study. Samples are broken down by subject groups. : PersA\_ICS Persistent asthma with ICS use PersA\_no\_ICS Persistent asthma without ICS use, ClinR Clinical Remission, ComR Complete Remission, H Healthy Controls. A) The middle tiers (light blue) show drop out of samples due to failed DNA extraction (no DNA), failure to meet the MethylAid QC criteria (MethylAid QC) and genotype mismatch between methylation array and independent SNP array (genotype mismatch). B) The middle tiers (light blue) show drop out of samples due to failed RNA extraction (no RNA), failure during sample processing (sample processing) and failure to meet QC criteria after sequencing (QC).

**Figure 2:** Summary statistics of the effect of adding cell type composition on differential methylation of a subset of CpG-sites. Figure (A) shows the  $-\log_{10}$  transformed  $P$ -values from the contrasts that were assessed in the manuscript. The leftmost four CpG-sites are the tophits from the contrast remission *versus* asthma and the remaining sites come from the contrast remission *versus* healthy. See the MS for details. Plotted are the uncorrected  $P$ -values (red, also reported in Table 2A and 2B) and the  $P$ -values from the analysis including surrogate variables (blue). Figure (B) shows the  $-\log_{10}$  transformed  $P$ -values for the surrogate variables for the same CpG-sites as in (A).

A)

B)

**Figure 3:** Quantile-quantile plots of observed  $P$ -values plotted against the expected  $P$ -values from a uniform distribution. Plots show data from the contrast (A) remission versus asthma and (B) remission versus healthy. The lambda values from chi-square statistics are reported in the figures. Lambda values differing from 1 indicate systematic bias, but may have a biological source (e.g. driven by differences cell composition).

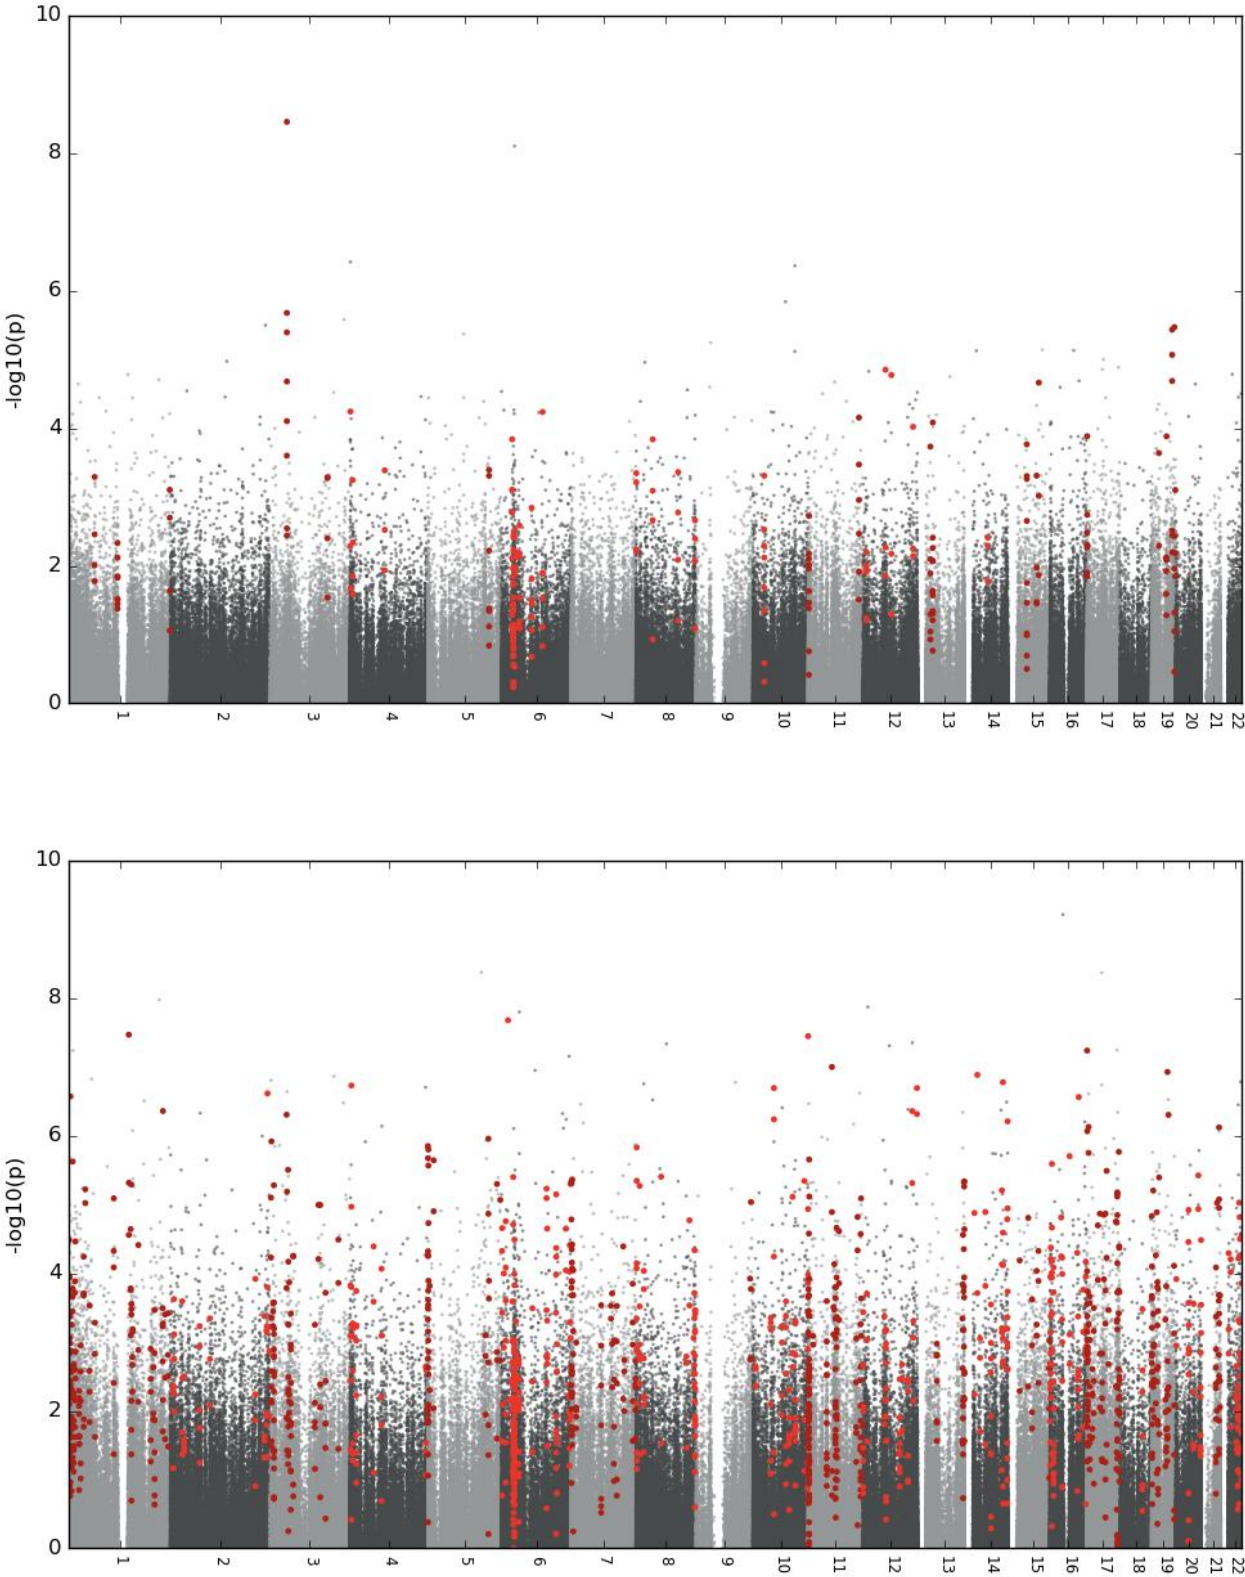

A)

B)

**Figure 4:** Manhattan plots of DMRs as output of the comb-p program. A) Asthma versus Remission. B) Remission versus Healthy.

**Figure 5:** Overlap in genomic position of individual CpGs with DMRs. A) Asthma versus Remission. B) Remission versus Healthy.

## Supplementary Tables

Table 1A-B: limma output R-PersA\_no\_ICS and R-H for all CpG-sites nominally significant  $P\text{-Value} < 0.05$ . Toptables of CpG-sites are annotated with genes with significantly correlated transcript abundance ( $P < 0.001$ ).

Table 2A-B: Final comb-p output table of regions passing the filter

Table 3: P-values from limma's Mean Rank Gene Set Test. Input were the t-statistics from MatrixEQTL DNA methylation M-values versus gene expression for the 14 CpG-sites in the table rows. The columns show the twenty gene sets corresponding to genes expressed by four major cell type clusters.
